Fatigue Analysis Equations

For each load case and fatigue point, OrcaFlex calculates damage values as follows:. The response, under that load case at that fatigue point, is calculated. For homogeneous pipes the ZZ stress variable is used. For stress factor fatigue then the stress is calculated based on the stress factors.For mooring fatigue the response variable is effective tension.

Fatigue analysis: How damage is calculated

The Ramberg-Osgood equation describes the nonlinear relationship between the stress and the strain of a material around the yield point of the material. The equation is often used in conjunction with Neuber’s rule, to estimate plastic stress and strain based on linear stress calculation results.. The Ramberg-Osgood relationship. Hooke’s law states that below the yield point, the stress is ...

Analysis of fatigue data requires techniques from statistics, especially survival analysis and linear regression. The progression of the S-N curve can be influenced by many factors such as stress ratio (mean stress), [32] loading frequency, temperature , corrosion , residual stresses, and the presence of notches.

Fatigue (material) - Wikipedia

Fatigue analysis itself usually refers to one of two methodologies. The stress-life (or S-N method), is commonly referred to as the total life method since it makes no distinction between initiating or growing a crack. This was the first fatigue analysis method to be developed over 100 years ago.

Constant life lines are used for finite life fatigue analysis. Long life, or infinite life, is usually defined at 10^6 – 10^8 cycles. When the expected life of the component is less than long life, then a finite fatigue line can be drawn and higher mean and alternating stresses can be applied to the component without a fatigue failure.

A crack growth equation is used for calculating the size of a fatigue crack growing from cyclic loads. The growth of fatigue cracks can result in catastrophic failure, particularly in the case of aircraft. A crack growth equation can be used to ensure safety, both in the design phase and during operation, by predicting the size of cracks.

The Goodman relation also called a Goodman diagram, a Goodman-Haigh diagram, a Haigh diagram or a Haigh-Soderberg diagram, is an equation used to quantify the interaction of mean and alternating stresses on the fatigue life of a material. The equation is typically presented as a linear curve of mean stress vs. alternating stress that provides the maximum number of alternating stress cycles a ...

The NASGRO equation is the most general of the crack growth equations. ... In this case, fatigue crack growth analysis is key to safe operation of the system. This approach to allowing and accounting for a safe level of crack growth during the operation of the system is referred to as damage-tolerant design.

Fatigue Strength Equation (cont.) Equation 2 is now subtracted from two times equation 1. This eliminates b from the resulting equation permitting “a” to be determined. It is seen that the final result for “a” is dependent on the tensile strength and the endurance limit of the material in question.

The larger the Kt, the lower the fatigue limit and the steeper the S-N curve (smaller value of k in the S-N curve equation (Sa^k)*N=c). Very often, structural analysis is performed using Finite Element Analysis (FEA). Such an analysis gives local strains and stresses. Quite often, FEA is used because of the complexity of the structure.

Qianfan Xin, in Diesel Engine System Design, 2013. HCF. High cycle fatigue is a type of fatigue caused by small elastic strains under a high number of load cycles before failure occurs. The stress comes from a combination of mean and alternating stresses. The mean stress is caused by the residual stress, the assembly load, or the strongly non-uniform temperature distribution.

In the stress-life or strain-life approaches, equation [7.2] takes the form of. [7.3] F R (τ) = A + B { log [N (τ)] } C. where A, B, and C are constants (C is usually set to be 1), N (τ) denotes time (or cycles) to failure. Equation [7.3] can be obtained by curve-fitting using fatigue testing data on specimens.

The fatigue life equation presented in this section is based on the Palmgren-Miner Fatigue model, which uses an S - N model based on the American Welding Society modified (AWS-X) fatigue curve of the form: (5.10)N = 6.48×10−8 Δε4 where N is the number of cycles to failure and Δε is the strain range in each cycle.

The rainflow-counting algorithm is used in the analysis of fatigue data in order to reduce a spectrum of varying stress into an equivalent set of simple stress reversals. The method successively extracts the smaller interruption cycles from a sequence, which models the material memory effect seen with stress-strain hysteresis cycles. This simplification allows the fatigue life of a component ...
